The myofibroblast is a key cell for the connective tissue remodeling that takes place during wound healing and fibrosis development. On this basis, the myofibroblast may represent a new important target for improving the evolution of such diseases as hypertrophic scars, and liver, kidney or pulmonary fibrosis.

The Myofibroblast

After tissue injury, fibroblasts differentiate into contractile and secretory myofibroblasts that contribute to tissue repair during wound healing, but that can severely impair organ function when contraction and extracellular matrix (ECM) protein secretion become excessive, such as in hypertrophic scars, scleroderma, and Dupuytren's disease as well as in heart and kidney fibrosis. 1, 2, 3

Wound healing - Wikipedia

Scarless wound healing is a concept based on the healing or repair of the skin (or other tissue/organs) after injury with the aim of healing with subjectively and relatively less scar tissue than normally expected.
